Evidence prioritisation of SINAN-recorded underlying conditions

Evidence was separated into independent primary studies, overlapping Brazilian surveillance studies, and evidence syntheses.

Condition	Independent primary evidence	Overlapping Brazilian evidence	Evidence synthesis	Final analysis role
Diabetes mellitus	H ↑ D imprecise	H ↑ D ↑	D ↑	CORE
Hypertension	S ↑; H mixed D imprecise	H ↑ D ↑	D ↑	CORE
Chronic kidney disease	H ↑	H ↑ D ↑	D ↑	CORE
Hepatopathy / liver diseas	No direct evidence	D ↑	Limited	SECONDARY
Autoimmune disease	No direct evidence	H ↑ D ↑	Sparse	SECONDARY
Haematological disease	Sparse	Sparse	Sparse	NOT PRIORITISED
Peptic ulcer disease	Sparse	H mixed / no clear increase	Sparse	NOT PRIORITISED

H = hospitalisation; S = severe disease; D = death; ↑ = evidence of increased risk.

Brazilian surveillance studies overlapping the present SINAN population were retained as relevant evidence; they were not counted as independent external replication.

Evidence syntheses were supportive but not independent replication because they could include primary studies represented elsewhere in the evidence map.

Final prioritisation reflects overall recurrence and relevance across source types, not publication counts.
